## The Friedmann–Lemaître model with quintessence and phantom Liouville fields

- Dynamical Dark Energy has been modelled by quintessence<sup>1</sup> and phantom<sup>2</sup> matter, which can be realised by minimally-coupled real scalar fields with  $\ell = \pm 1$ <sup>3</sup>

$$\mathcal{S}_L = \int d^4x \sqrt{-g} \left\{ -\ell \frac{g^{\mu\nu}}{2} (\partial_\mu \phi)(\partial_\nu \phi) - \mathcal{V}(\phi) \right\}. \quad (1)$$

- The Liouville field<sup>4</sup>  $\mathcal{V}(\phi) = V e^{\lambda\phi}$  is of interest, where  $\lambda, V \in \mathbb{R}$ .
- Assume a flat Robertson–Walker metric  $g_{\mu\nu} dx^\mu dx^\nu = -N^2(t) dt^2 + \varkappa e^{2\alpha(t)} d\Omega_{3F}^2$ , where  $\varkappa := 8\pi G$ ,  $d\Omega_{3F}^2 := d\chi^2 + \chi^2(d\theta^2 + \sin^2 \theta d\varphi^2)$ , and  $N$  lapse function.
- The total action reads  $\mathcal{S} := \mathcal{S}_{EH} + \mathcal{S}_{GHY} + \mathcal{S}_L = \int d\Omega_{3F}^2 \int dt L$ , where

$$L := \varkappa^{3/2} N e^{3\alpha} \left( -\frac{3}{\varkappa} \frac{\dot{\alpha}^2}{N^2} + \ell \frac{\dot{\phi}^2}{2N^2} - V e^{\lambda\phi} \right). \quad (2)$$

# Introduction

## Highlights

### Integrability

Implicit trajectories can be obtained explicitly; the minisuperspace Wheeler–DeWitt equation can be integrated exactly.

### Self-adjointness

The Hamiltonian can be asymmetric; imposing self-adjointness leads to removal of degeneracy and discretisation of levels.

### Semi-classical wave functions

Semi-classical wave functions can be constructed by the principle of constructive interference, the Wentzel–Kramers–Brillouin approximation and numerical methods.

The inner product and wave packet

5. Conclusions

# Decoupling the variables

Via orthogonal transformation

- By rescaling  $\bar{N} := Ne^{-3\alpha}$  and the orthogonal transformation

$$\begin{pmatrix} \alpha(t) \\ \phi(t) \end{pmatrix} = \frac{\varsigma}{g} \begin{pmatrix} \lambda & -\ell\kappa \\ -6 & \lambda \end{pmatrix} \begin{pmatrix} \varsigma_\beta \cdot \beta(t) \\ \varsigma_\chi \cdot \chi(t) \end{pmatrix} \quad \text{where } \varsigma_\beta, \varsigma_\chi = \pm 1, \quad (3)$$

the effective Lagrangian eq. (2) can be decoupled ( $\varsigma_\beta = \varsigma_\chi = +1$  from now on)

$$L = \kappa^{3/2} \bar{N} \left( -\varsigma \frac{3}{\kappa} \frac{\dot{\beta}^2}{\bar{N}^2} + \ell \varsigma \frac{\dot{\chi}^2}{2\bar{N}^2} - V e^{g\chi} \right), \quad (4)$$

where  $\Delta := \lambda^2 - 6\ell\kappa$ ,  $\varsigma := \operatorname{sgn} \Delta$  and  $g := \varsigma \sqrt{|\Delta|} \equiv \varsigma \sqrt{3\Delta}$ .

- The Euler–Lagrange equations with respect to  $\bar{N}$ ,  $\beta$  and  $\chi$  will be called the modified first, second Friedmann equations and the Klein–Gordon equation, respectively.
- Since  $\beta(t)$  is cyclic, its conjugate momentum  $p_\beta$  is conserved<sup>5</sup>, and the modified second Friedmann equation can be readily integrated.

---

<sup>5</sup>The same first integral has been found in C. Lan, PhD thesis, Saint Petersburg State University, 2016, <https://search.rsl.ru/ru/record/01006663434>, A. A. Andrianov et al., *Theor. Math. Phys.* **184**, 1224–1233 (Sept. 2015), in canonical formalism.

# Integration and the implicit trajectories

- For  $p_\beta \neq 0$ , fixing the *implicit gauge*  $\bar{N} = -6\sqrt{\nu}\dot{\beta}/p_\beta$ , the modified first Friedmann equation can be integrated, yielding the **implicit** trajectory

$$e^{g\chi} = \frac{p_\beta^2}{12\nu^2|V|} s^2 \left( \sqrt{\frac{3}{2\nu}} g(\beta - \beta_0) \right), \quad (5)$$

in which  $v := \operatorname{sgn} V$ ,  $(\operatorname{sgn}, \operatorname{sgn})$  means  $(\ell, sv)$ , and

$$\begin{aligned} s_{++}(\gamma) &:= \operatorname{sech}(\gamma), & s_{+-}(\gamma) &:= \operatorname{csch}(\gamma), \\ s_{-+}(\gamma) &:= \sec(\gamma), & s_{--}(\gamma) &:= i \csc(\gamma). \end{aligned} \quad (6)$$

- The integral for the phantom model with  $(-, +)$  is periodic for  $\beta$  with  $T_\beta = \sqrt{\frac{2\nu}{3}} \frac{2\pi}{g}$ .
  - The integral for the phantom model with  $(-, -)$  is not real.
  - The trajectories can be parametrised by  $\beta$ , inspiring recognising  $\beta$  as a ‘time variable’.
- For  $p_\beta = 0$ , integrating the modified second Friedmann equation yields  $\beta \equiv \beta_0$  or  $\phi - \phi_0 = -\ell \lambda \alpha / \nu^6$ , which is the well-known power-law special solution<sup>7</sup>.

<sup>6</sup>It only works for  $(+, -)$  or  $(-, +)$  if one checks consistency with the modified first Friedmann equation.

<sup>7</sup>For instance, A. R. Liddle, D. H. Lyth, *Cosmological Inflation and Large-Scale Structure*, (Cambridge University, 2000) , ch. 3.

5. Conclusions

# Dirac quantisation

- The primary Hamiltonian and the Hamiltonian constraint<sup>8</sup> reads

$$H^p = \bar{N} H_{\perp} + v^{\bar{N}} p_{\bar{N}}, \quad (7)$$

$$H_{\perp} := -\beta \frac{p_{\beta}^2}{12\nu^{1/2}} + \ell \beta \frac{p_{\chi}^2}{2\nu^{3/2}} + \nu^{3/2} V e^{g\chi}. \quad (8)$$

- Applying the Dirac quantisation rules with the Laplace–Beltrami operator ordering<sup>9</sup>, one gets the minisuperspace Wheeler–DeWitt equation with  $(\beta, \chi)$

$$0 = \widehat{H}_{\perp} \Psi(\beta, \chi) := \left( \beta \frac{\hbar^2}{12\nu^{1/2}} \partial_{\beta}^2 - \ell \beta \frac{\hbar^2}{2\nu^{3/2}} \partial_{\chi}^2 + \nu^{3/2} V e^{g\chi} \right) \Psi. \quad (9)$$

- Equation (9) is Klein–Gordon-like, hyperbolic for  $\ell = +1$  and *elliptic* for  $\ell = -1$ .

# Integration of the Wheeler–DeWitt equation

The quantum-mechanical analogy

- Fourier transforming  $\beta$  to  $k_\beta \in \mathbb{R}$  yields the time-independent Schrödinger equation

$$E\psi(x) := \ell \frac{\hbar^2 \tilde{g}^2 \nu^2}{8M_P} \psi = \widehat{H}_{\text{eff}} \psi := \left( -\frac{\hbar^2}{2M_P} \partial_x^2 + \widehat{V}_{\text{eff}}(x) \right) \psi, \quad V_{\text{eff}} := \ell \wp \widetilde{V} e^{\tilde{g}x}, \quad (10)$$

in which  $M_P := \sqrt{\frac{\hbar}{\nu}}$ ,  $x := \sqrt{\hbar}\wp \cdot \chi$ ,  $\widetilde{V} := M_P^{-3}|V| \geq 0$ , and  $\nu = \sqrt{\frac{2\nu}{3}} \frac{|k_\beta|}{g} \geq 0$ .

- $V_{\text{eff}}$  is a special case of the Morse potential<sup>10</sup>.
- Let  $e^{2\tilde{x}} = 8M_P \widetilde{V}/\hbar^2 \tilde{g}^2 \cdot e^{\tilde{g}x}$

	$E \geq 0$	$E < 0$
$V_{\text{eff}} > 0$	$(+, +); K_{\frac{1}{2}\nu}(e^{\tilde{x}})$	$(-, -); \text{none}$
$V_{\text{eff}} < 0$	$(+, -); F_{\frac{1}{2}\nu}(e^{\tilde{x}}), G_{\frac{1}{2}\nu}(e^{\tilde{x}})$	$(-, +); J_\nu(e^{\tilde{x}})$

<sup>10</sup>P. M. Morse, *Phys. Rev.* **34**, 57–64 (July 1929), D. M. Gitman *et al.*, *Self-adjoint Extensions in Quantum Mechanics*, (Birkhäuser, 2012).

# The self-adjointness of unbounded operators

## The general theory

- Even in quantum geometrodynamics, the self-adjointness of the matter Hamiltonian is desirable, which is typically an unbounded operator in the Hilbert space  $\mathbf{F}$  endowed with the Schrödinger inner product  $(\cdot, \cdot)_S$ .
- Mathematically, an *unbounded* operator  $H$  is characterised not only by its action on a vector, but also by its domain  $\text{Dom}(H) \subsetneq \mathbf{F}^{11}$ .
- In addition to the *symmetry*  $(H^\dagger \phi_1, \phi_2) \equiv (\phi_1, H\phi_2)$ , the self-adjointness of an unbounded operator also requires  $\text{Dom}(H^\dagger) = \text{Dom}(H)$ .
- For quantum systems not bounded below, not only the self-adjointness, but also the symmetry of the Hamiltonian is not guaranteed automatically.
- Even when one could find a  $\text{Dom}_0(H)$  such that  $H$  is symmetric, one would still be left with  $\text{Dom}_0(H^\dagger) \supsetneq \text{Dom}_0(H)$  in general.
- Sloppily speaking, the process of extending  $\text{Dom}(H)$  such that  $\text{Dom}(H^\dagger) = \text{Dom}(H)$  is called **self-adjoint extension**<sup>12</sup>; if the extension is unique, the operator is called *essentially self-adjoint*.

# The self-adjointness of the Hamiltonian

Results for the Liouville potential<sup>16</sup>

- For  $V_{\text{eff}} > 0$ :  $\widehat{H}_{\text{eff}}$  is **essentially self-adjoint**<sup>13</sup>.
  - For the quintessence model  $(+, +)$ , nothing special.
- For  $V_{\text{eff}} < 0$ :  $\widehat{H}_{\text{eff}}$  admits **a family of self-adjoint extensions**.
  - For the quintessence model  $(+, -)$ , the generalised eigenfunction is a linear combination of F and G, and **the degeneracy is removed**.
  - For the phantom model  $(-, +)$ , the eigenfunctions are **discretised**

$$\psi_{+, \nu} \propto J_\nu, \quad \nu = 2n + a_<, \quad n \in \mathbb{Z}_\geq, \quad (11)$$

and the corresponding full wave-functions are Bloch-periodic

$\Psi_{+, n}(\beta, \chi) = e^{i\pi a_<} \Psi_{-, n}(\beta + T_\beta, \chi)$ . Imposing (anti-)periodic boundary condition would fix  $a_< = 0$  (1).

- The self-adjointness has been discussed in quantum cosmology in e.g.<sup>14</sup> (in the operator ordering scenario) and more recently in<sup>15</sup>.

The Wentzel–Kramers–Brillouin approximation  
The inner product and wave packet

5. Conclusions

# Matching quantum number with classical first integral

Principle of constructive interference;  $(+, +)$  as the example

- Write the mode function in the Wentzel–Kramers–Brillouin form  
 $\Psi_\nu(\beta, \chi) \sim \sqrt{\rho(\beta, \chi)} \exp\left\{\frac{i}{\hbar} S(\beta, \chi)\right\}$ . For  $S/\hbar \gg 1$  and  $\nu \gg 1$ ,  $S(\beta, \chi)$  becomes the Hamilton principle function in the leading-order approximation, which is stationary with respect to the variation of integral constants  $\partial S / \partial \nu = 0$ .
- Fixing  $\nu/\sigma > 1$ ,

$$K_{\frac{1}{2}\nu}(\sigma) \sim \frac{\sqrt{2\pi} \cos\left(\sqrt{\nu^2 - \sigma^2} - \nu \arccos \frac{\nu}{\sigma} - \frac{\pi}{4}\right)}{(\nu^2 - \sigma^2)^{1/4} e^{\pm\nu/2}} + O\left(\frac{1}{\sigma}\right). \quad (12)$$

- Applying *the principle* to the phase of  $\Psi_\nu(\sigma)$ , one has  $\sigma/\nu = \operatorname{sech}(\beta_\beta \gamma)$ , which matches the trajectory if  $\hbar k_\beta \equiv \hbar \sqrt{\frac{3}{2\nu}} g\nu = p_\beta$ .
- Fixing  $\nu/\sigma < 1$ , the asymptotic expansion is not oscillatory, but exponential; it is not within the Wentzel–Kramers–Brillouin regime.
- The conclusions also hold for  $F_{\frac{1}{2}\nu}(\sigma)$ ,  $G_{\frac{1}{2}\nu}(\sigma)$  for  $(+,-)$ , and  $J_\nu(\sigma)$  for  $(-,+)$ .

# Inner products for wave functions

Schrödinger and Mostafazadeh inner product

- A common starting point is the Schrödinger product<sup>17</sup>

$$(\Psi_1, \Psi_2)_S := \int d\chi \Psi_1^*(\beta, \chi) \Psi_2(\beta, \chi); \quad (13)$$

- $(\Psi, \Psi)_S$  is positive-definite, and the integrand  $\rho_S(\beta, \chi)$  is non-negative
- The corresponding Schrödinger current is real but does not satisfy continuity equation

- Mostafazadeh<sup>18</sup> found an inner product for self-adjoint  $\mathbb{D}$  with positive spectrum:

$$(\Psi_1, \Psi_2)_M^\kappa := \kappa \left\{ (\Psi_1, \mathbb{D}^{+1/2} \Psi_2)_S + (\partial_\beta \Psi_1, \mathbb{D}^{-1/2} \partial_\beta \Psi_2)_S \right\}, \quad \kappa > 0. \quad (14)$$

- Real power of  $\mathbb{D}$  is defined by spectral decomposition
- It can be shown<sup>19</sup> that the density

$$\varrho_M^\kappa := \kappa \left\{ |\mathbb{D}^{+1/4} \Psi|^2 + |\mathbb{D}^{-1/4} \partial_\beta \Psi|^2 \right\} \quad (15)$$

- is equivalent to the integrand  $\rho_M^\kappa$  up to a boundary term  $\int d\chi \varrho_M^\kappa = \int d\chi \rho_M^\kappa \equiv (\Psi_1, \Psi_2)_M^\kappa$
- is non-negative
- The corresponding current  $\vec{\mathcal{J}}_M^\kappa$  is real but not conserved<sup>20</sup>.

# Wave packets of Gaussian amplitude for continuous spectrum

## Quintessence models

- It is difficult to find an amplitude such that the wave packet is Gaussian
- Instead, one can choose a Gaussian amplitude

$$A(\nu; \bar{\nu}, \sigma) := \left( \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{(\nu - \bar{\nu})^2}{2\sigma^2}\right) \right)^{1/2} \quad (16)$$

- In<sup>21</sup>,  $A(\nu; \bar{\nu}, \sigma/\sqrt{2})$  was chosen.

# Outline

1. Introduction
2. The classical model and the implicit trajectories  
Lagrangian formalism and the first integral

3. Dirac quantisation and the self-adjointness of Hamiltonian  
Dirac quantisation and the quantum-mechanical analogy  
The self-adjointness of Hamiltonian

4. The semi-classical wave packets  
The Wentzel–Kramers–Brillouin approximation  
The inner product and wave packet

5. Conclusions

# Highlights

- An **integral of motion** was found for Liouville cosmological models.
- **Implicit trajectories** in minisuperspace were obtained.
- The levels of phantom Liouville model were found to be **discrete** due to the Hermiticity requirement of observables.
- The semi-classical quantum mode functions and wave packets was compared directly with the classical trajectory.

## Issues

- In  $(+, -)$  and  $(-, +)$ , wave packets contain multiple branches; however, the classical universe runs only on one trajectory.
- Quantum-corrected  $\bar{k}_\beta$  is to be understood.
- Wave packets with Gaussian profile are to be constructed, instead of inserting Gaussian / Poissonian amplitude artificially.
- A normalising  $\kappa$  for  $(\cdot, \cdot)_M^\kappa$  is to be evaluated, otherwise a quantitative comparison of  $(\cdot, \cdot)_S$  and  $(\cdot, \cdot)_M^\kappa$  is not possible.

# Outlook

- Beyond isotropy: generalise to Bianchi models
  - Bianchi Type-I: a natural extension, **under investigation**
- Beyond homogeneity: cosmological perturbation, **under investigation**
- Beyond single field
  - Two exponential potentials:  $|V_1| = |V_2|$  and special  $\lambda_i$
  - Multiple Liouville fields: mixing kinetic terms needed<sup>23</sup>
- Beyond classic matter
  - $PT$ -symmetric Liouville field<sup>24</sup>: may cross the phantom divide  $w = -1$ .

$$s \frac{p_\beta^2}{12} \left( -\ell \frac{\varkappa^{1/2}}{6} \left( \frac{d\chi}{d\beta} \right)^2 + \varkappa^{-1/2} \right) - \varkappa^{3/2} V e^{g\chi} = 0, \quad (18)$$

one can substitute

$$\gamma := \sqrt{\frac{3}{2\varkappa} g\beta}, \quad \tilde{\sigma}^2 := \frac{p_\beta^2}{12\varkappa^2 |V|} e^{-g\chi}, \quad (19)$$

to get

$$\left( \frac{d\tilde{\sigma}}{d\gamma} \right)^2 + \ell(s\upsilon - \tilde{\sigma}^2) = 0 \quad \Rightarrow \quad \frac{d\gamma}{d\tilde{\sigma}} = \pm \frac{1}{\sqrt{\ell(-s\upsilon + \tilde{\sigma}^2)}}, \quad (20)$$

which is of the standard inverse hyperbolic / trigonometric form **except for  $(-, -)$** .

# Integration of the separated minisuperspace WDW equation

In order to integrate the separated minisuperspace Wheeler–DeWitt equation

$$\mathbb{D}\psi(\chi) = k_\beta^2 \psi(\chi), \quad \mathbb{D} := -\ell \frac{6}{\varkappa} \partial_\chi^2 + \mathfrak{s} v \frac{12\varkappa^2 |V|}{\hbar^2}, \quad (\text{?? rev.})$$

one can transform

$$\nu := \sqrt{\frac{2\varkappa}{3}} \frac{k_\beta}{g}, \quad \sigma^2 := \frac{8\varkappa^3 |V| e^{g\chi}}{\hbar^2 g^2}, \quad (\text{?? rev.})$$

to get

$$\sigma^2 \psi''(\sigma) + \sigma \psi'(\sigma) + \ell(\nu^2 - \mathfrak{s} v \sigma^2) \psi(\sigma) = 0, \quad (21)$$

which is of the standard Besselian form.
